

Ramsey Theory: Example Sheet 1

Otto Pyper

1. Let $f : [n] \rightarrow [m] \cup \{*\}$ such that $f^{-1}(\{*\}) \neq \emptyset$. We can identify f with a combinatorial line by $I = \{i : f(i) = *\}$ and for $i \notin I$, $x_i = f(i)$; similarly, given a combinatorial line L there is a unique such f that represents it.

So the number of combinatorial lines in $[m]^n$ is just the number of such f s, which equals $(\#\{f : [n] \rightarrow [m] \cup \{*\}\} - \#\{f : [n] \rightarrow [m]\}) = (m+1)^n - m^n$.

2. Induction on k . Base case: $\text{HJ}(2, 1) = 1$ since the single combinatorial line must be monochrome, and the empty set has a 1-colouring with no monochromatic line.

Now assume that $\text{HJ}(2, k-1) = k-1$. Observe that $(0, 0, \dots, 0) \in [2]^k$ forms a combinatorial line with any other point, so $[2]^k \setminus \{(0, \dots, 0)\}$ must be $k-1$ -coloured. Hence $[2]^{k-1} \times \{1\}$ is $(k-1)$ -coloured. The colouring on $[2]^{k-1} \times \{1\}$ induces a colouring on $[2]^{k-1}$, which has a monochromatic combinatorial line $L = \{\underline{x}_1, \underline{x}_2\}$, and so $\{\underline{x}_1 1, \underline{x}_2 1\}$ is a monochromatic combinatorial line in $[2]^k$. Hence $\text{HJ}(2, k) \leq k$.

Moreover, $\text{HJ}(2, k) > k-1$; we can k -colour $[2]^{k-1}$ by $c(x_1, \dots, x_{k-1}) = x_1 + \dots + x_{k-1}$, where the colours are the set $\{0, \dots, k-1\}$. This contains no monochromatic line. Hence $\text{HJ}(2, k) = k$ for all k .

3. 2-colour $A^{(4)}$ by giving $B \subseteq A$ the colour red if any of the points lies within the triangle formed by the other three, and blue otherwise. This is unambiguous since no three points are colinear.

Then by Ramsey's Theorem there exists a monochromatic set C of size $k = 2021$. C is then clearly convex, but this is surprisingly difficult to actually prove.

[from class: consider convex hull, take point in hull not on boundary from set, triangulate]

4. Suppose that this is true, and let $c_n : \mathbb{N}^{(n)} \rightarrow [2]$ be the 2-colouring whereby A is red if $n \in A$, and blue otherwise. If $M \subseteq \mathbb{N}$ is infinite and monochromatic under c_n , then it cannot contain n since then its colour must be red, but there of course exists $A \subseteq M \setminus \{n\}$ with $|A| = n$, and then $c_n(A)$ is blue.

So let $c = \bigcup c_n$ be the 2-colouring of $\bigcup \mathbb{N}^{(n)}$. Then there exists an infinite $M \subseteq \mathbb{N}$ such that, for each r , c is constant on $M^{(r)}$. But for each r , $c \upharpoonright M^{(r)} = c_r$, and since c_r is constant on M we conclude that $r \notin M$. But r was arbitrary, so M is empty, contradiction.

5. For $u, v \in \{0, 1\}^{\mathbb{N}}$, let $d(u, v) = 2^{-m}$, where m is the least $n \geq 0$ such that $u \upharpoonright n \neq v \upharpoonright n$. d is then a metric on $\{0, 1\}^{\mathbb{N}}$, with the same induced topology. Hence it will suffice to show this space is sequentially compact.

Let $(x_n)_{n \in \mathbb{N}}$ be a sequence of points in $\{0, 1\}^{\mathbb{N}}$. There must be some $a_1 \in \{0, 1\}$ such that $x_n \upharpoonright 1 = a_1$ for infinitely many n . Call this set A_1 . Repeat within A_1 to find a_2 and hence A_2 , and continue ad infinitum.

We obtain a sequence $(a_k)_{k \geq 1}$ whose concatenation a is an element of $\{0, 1\}^{\mathbb{N}}$. Then for all $m \in \mathbb{N}$, there exists an $n(m) \in \mathbb{N}$ with $x_n \upharpoonright m = a \upharpoonright m$. So these x_n converge to a ; hence the space is sequentially compact, and hence is compact.

6. Pretty mechanical, standard stuff. Need to get the hang of the bound though.

7. Just two-colour $\mathbb{N}^{(2)}$ and find an infinite mono subset; this obviously has such a finite set M within it. Then use product argument to show this is all we need.
8. Hales-Jewett clumps for each number of colours k ; so the answer is no.
9. No, by that stupid colouring (pick irrational in $[0, 1]$, keep adding it or something).
10. With choice: false. Wellorder \mathbb{R} ($<_\alpha$) and colour $\{a, b\}$ red if their order in the wellorder agrees with their natural order in \mathbb{R} . A monochromatic subset is then $M = \{a_i : i \in I\}$ with $a_i < a_j$ for $i < j$ such that either of the following holds:
 - for all $i < j$, $a_i <_\alpha a_j$, or
 - for all $i < j$, $a_j <_\alpha a_i$

But then if I is uncountable, then in the first case M is well-ordered, and in the second case $-M$ is wellordered; in either case we have an uncountable wellordered subset of \mathbb{R} . Contradiction.

Without choice: it is consistent in ZF that there are countable pairwise disjoint sets A_n such that $\bigcup_{n \in \mathbb{N}} A_n$ is uncountable. Then 2-colour the edges of $\bigcup A_n$ by making $\{a, b\}$ red if they lie in the same A_n , and blue otherwise. We end up with a countable infinite of red islands, with the edges between all islands being blue. This has no uncountable monochromatic subset.
